(54) Driving method for recording head

(57) A head (1) and a head (2) are fixed to the opposed surfaces of a substrate (3). In the head (1), ink nozzles (41 to 49) are arranged at intervals of pitch $2P$ in the main scanning direction and divided into three sets of ink nozzles (41, 44, . . . , 42, 45, . . . , and 43, 46, . . .) so that they are spaced at intervals of pitch D in the sub-scanning direction. In the head (2) as well, ink nozzles (51 to 59) are arranged at intervals of pitch $2P$ in the main scanning direction and divided into three sets of ink nozzles (51, 54, . . . , 52, 55, . . . , and 53, 56, . . .) so that they are spaced at intervals of pitch D in the sub-scanning direction. The corresponding two ink nozzles in the heads (1 and 2) are offset from each other by pitch P in the main scanning direction. Assuming the distance between the nozzles (41, and 51) to be d , when the difference $(d - n \times 3D)$ (n is an integer) is larger than $D/2$, the timing of ink projection from each set of ink nozzles in the head (2) is changed to reduce the difference below $D/2$.

FIG. 3

EP 0 938 976 A1

FIGS. 6A and 6B show printed dots in the first embodiment before and after correction of alignment error;

FIGS. 7A and 7B show printed dots in the first embodiment before and after correction of alignment error;

FIG. 8 shows an ink jet head driver circuit in the first embodiment;

FIGS. 9A and 9B are diagrams for use in explanation of methods of measuring the amount L of misalignment between dot arrangements in the first embodiment;

FIG. 10 shows an ink jet head driver circuit in a second embodiment of the present invention;

FIG. 11 shows an arrangement of printed dot data in the second embodiment;

FIGS. 12A through 12F show a relationship between driving timing and printed dot data in the second embodiment;

FIGS. 13A through 13F show another relationship between driving timing and printed dot data in the second embodiment;

FIG. 14 shows an arrangement of ink nozzles of each ink jet head in a third embodiment of the present invention;

FIGS. 15A through 15E show drive voltage waveforms used in the third embodiment;

FIGS. 16A and 16B show printed dots in the third embodiment before and after correction of dot alignment error;

FIG. 17 is a schematic representation of a print head assembly according to a fourth embodiment of the present invention;

FIG. 18 shows an arrangement of ink nozzles of each ink jet head in the fourth embodiment of the present invention;

FIGS. 19A and 19B show printed dots in the third embodiment before and after correction of dot alignment error;

FIG. 20 is a schematic representation of a print head assembly according to a fifth embodiment of the present invention;

FIG. 21 shows an arrangement of ink nozzles of each ink jet head in the fifth embodiment;

FIG. 22 is a schematic representation of a print head assembly according to a sixth embodiment of the present invention;

FIG. 23 shows an arrangement of ink nozzles of each ink jet head in the sixth embodiment;

FIG. 24 is a schematic representation of a print head assembly according to a seventh embodiment of the present invention;

FIGS. 25A and 25B show a configuration of the ink jet head used in each of the embodiments of the present invention;

FIGS. 26A and 26B show another configuration of the ink jet head used in each of the embodiments of the present invention;

FIGS. 27A and 27B show still another configuration of the ink jet head used in each of the embodiments of the present invention; and

FIG. 28 shows another example of a staggered arrangement of ink nozzles.

[0012] As shown in FIG. 1, ink jet heads 1 and 2, each with a large number of ink chambers, are fixed with adhesive to both sides of a substrate 3 which are parallel to each other to thereby form one recording head assembly.

[0013] The ink jet heads 1 and 2 and the substrate 3 are of such configuration as shown in FIG. 2.

[0014] That is, the ink jet heads 1 and 2 each with a large number of ink chambers are fixed to the respective sides of the substrate 3.

[0015] Ink supply tubes 1a and 2a are connected to the ink jet heads 1 and 2, respectively.

[0016] To portions of the ink jet heads 1 and 2 are respectively mounted connectors 1b and 2b with which cables 1c and 2c are connected respectively. Through these cables the ink jet heads 1 and 2 are supplied with drive voltages. P denotes a sheet of paper as a recording medium.

[0017] As shown in FIG. 3, the ink jet heads 1 and 2 are formed with ink nozzles 41 to 49, . . . and 51 to 59, . . . each corresponding to a respective one of the ink chambers. These ink nozzles are placed in a staggered arrangement for every three nozzles. That is, these ink nozzles 41 to 49, . . . of the ink jet head 1 are arranged at regular intervals of pitch 2P in the main scanning direction perpendicular to the direction of movement of the recording medium indicated by an arrow.

[0018] In the ink jet head 1, the ink chambers are divided into three sets each including every third head. That is, the ink nozzles 41, 44, 47, etc. form a first set. The nozzles 42, 45, 48, etc. form a second set, and the nozzles 43, 46, 49, etc. form a third set. The ink nozzles 41, 44, 47, etc. in the first set to which reference is made are arranged on a line 1a. The ink nozzles 42, 45, 48, etc. in the second set are arranged on a line 1b which is offset from the line 1a by given pitch D in the sub-scanning direction in which the recording medium travels. The ink nozzles 43, 46, 49, etc. in the third set are arranged on a line 1c which is offset from the line 1b by the pitch D in the sub-scanning direction.

[0019] In the ink jet head 2 as well, the ink chambers are divided into three sets each including every third head. That is, the ink nozzles 51, 54, 57, etc. form a first set. The nozzles 52, 55, 58, etc. form a second set, and the nozzles 53, 56, 59, etc. form a third set.

[0020] Each of the nozzles 51 to 59, etc. in the ink jet head 2, which are arranged at regular intervals of pitch 2P in the main scanning direction, is offset from a corresponding one of the nozzles 41 to 49, etc. by pitch P in the main scanning direction. The ink nozzles 51, 54, 57, etc. in the first set are arranged on a line 2a

ink jet head 1 are connected to a line 31 through analog switches 131, 134, . . . , respectively. The electrodes for applying voltages to the ink chambers 112, 115, . . . equipped with the ink nozzles 42, 45, . . . arranged on the line 1b of the ink jet head 1 are connected to a line 31 through analog switches 132, 135, . . . , respectively. The electrodes for applying voltages to the ink chambers 113, 116, . . . equipped with the ink nozzles 43, 46, . . . arranged on the line 1c of the ink jet head 1 are connected to a line 33 through analog switches 133, 136, . . . , respectively.

[0033] Electrodes for applying voltages to ink chambers 211, 212, 213, 214, 215, . . . in the ink jet head 2 are connected to ground through analog switches 221, 222, 223, 224, 225, . . . , respectively. The electrodes for applying voltages to the ink chambers 211, 214, . . . equipped with the ink nozzles 51, 54, . . . arranged on the line 2a of the ink jet head 2 are connected to a line 34 through analog switches 231, 234, . . . , respectively. The electrodes for applying voltages to the ink chambers 212, 215, . . . equipped with the ink nozzles 52, 55, . . . arranged on the line 2b of the ink jet head 2 are connected to a line 35 through analog switches 232, 235, . . . , respectively. The electrodes for applying voltages to the ink chambers 213, . . . equipped with the ink nozzles 53, . . . arranged on the line 2c of the ink jet head 2 are connected to a line 36 through analog switches 233, . . . , respectively.

[0034] The line 31 is connected to a waveform generator 37 for generating the drive voltage waveform shown in FIG. 4A and to each of first terminals 40a, 41a and 42a of selectors 40, 41 and 42. The line 32 is connected to a waveform generator 38 for generating the drive voltage waveform shown in FIG. 4B and to each of second terminals 40b, 41b and 42b of the selectors 40, 41 and 42. The line 33 is connected to a waveform generator 39 for generating the drive voltage waveform shown in FIG. 4C and to each of third terminals 40c, 41c and 42c of the selectors 40, 41 and 42.

[0035] The line 34 is connected to the common terminal of the selector 40. The line 35 is connected to the common terminal of the selector 41. The line 36 is connected to the common terminal of the selector 42.

[0036] Based on data to be printed from a printing data output circuit 43, the head drive circuit selectively turns on the analog switches 121 to 126 or 221 to 225 to thereby connect the electrodes of the ink chambers associated with the selectively turned-on analog switches to ground. Alternatively, the head drive circuit selectively turns on the analog switches 131 to 136 or 231 to 235 to thereby selectively apply the drive voltage waveform shown in FIG. 4A, 4B or 4C to each of the electrodes of the ink chambers associated with the selectively turned-on analog switches. When the analog switches 131 to 135 or 231 to 235 are selectively driven, droplets of ink are projected from the nozzles of the corresponding ink chambers.

[0037] The selective application of the drive voltage

waveform in FIG. 4A, 4B or 4C to each of the ink chamber electrodes is performed through the selectors 40, 41, and 42. That is, when the difference $(d - n \cdot 3D)$ is in the range defined by (1), the selector 40 selects the drive voltage waveform from the waveform generator 37 and outputs it onto the line 34. The selector 41 selects the drive voltage waveform from the waveform generator 38 and outputs it onto the line 35. The selector 42 selects the drive voltage waveform from the waveform generator 39 and outputs it onto the line 36.

[0038] When the difference $(d - n \cdot 3D)$ is in the range defined by (2), the selector 40 selects the drive voltage waveform from the waveform generator 38 and outputs it onto the line 34. The selector 41 selects the drive voltage waveform from the waveform generator 39 and outputs it onto the line 35. The selector 42 selects the drive voltage waveform from the waveform generator 37 and outputs it onto the line 36.

[0039] When the difference $(d - n \cdot 3D)$ is in the range defined by (3), the selector 40 selects the drive voltage waveform from the waveform generator 39 and outputs it onto the line 34. The selector 41 selects the drive voltage waveform from the waveform generator 37 and outputs it onto the line 35. The selector 42 selects the drive voltage waveform from the waveform generator 38 and outputs it onto the line 36.

[0040] Such control allows the alignment error between dot arrangements produced by the ink jet heads 1 and 2 in the sub-scanning direction to be corrected. That is, the dot misalignment in the sub-scanning direction is minimized, allowing high-resolution printing of good quality.

[0041] A method of detecting the difference $(d - n \cdot 3D)$ involves making printing in a specific pattern for testing as shown in FIG. 9A, observing the result of printing with a microscope, and measuring the spacing L between a line of dots n_1, n_2, \dots printed by the ink jet head 1 and a line of dots m_1, m_2, \dots printed by the ink jet head 2.

[0042] Alternatively, as shown in FIG. 9B, a testing specific pattern having a constant spacing may be printed and the spacing L between a line of dots m_1, m_2, \dots and the specific pattern may be determined.

[0043] Next, a second embodiment of the present invention will be described with reference to FIGS. 10 through 13. In these figures, like reference numerals are used to denote corresponding parts to those in the first embodiment and only different parts will be described.

[0044] In the second embodiment, as shown in FIG. 10, the waveform generators 37, 38 and 39 and the selectors 40, 41 and 42 in the first embodiment are replaced with programmable waveform generators 51 to 56. The programmable waveform generator 51 supplies its drive voltage waveform to analog switches 131, 134, etc. The programmable waveform generator 52 supplies its drive voltage waveform to the analog switches 132, 135, etc. The programmable waveform generator 53 supplies its drive voltage waveform to the analog

thus performing five-phase driving. That is, the ink nozzles 641, 646, etc. on the line 1d of the head 61 and the ink nozzles 651, 656, etc. on the line 2d of the head 62 are allowed to project droplets of ink at the times indicated in FIG. 15A. The ink nozzles 642, 647, etc. on the line 1e of the head 61 and the ink nozzles 652, 657, etc. on the line 2e of the head 62 project droplets of ink at the times indicated in FIG. 15B. The ink nozzles 643, 648, etc. on the line 1f of the head 61 and the ink nozzles 653, 658, etc. on the line 2f of the head 62 project droplets of ink at the times indicated in FIG. 15C. The ink nozzles 644, 649, etc. on the line 1g of the head 61 and the ink nozzles 654, 659, etc. on the line 2g of the head 62 project droplets of ink at the times indicated in FIG. 15D. The ink nozzles 645, 6410, etc. on the line 1h of the head 61 and the ink nozzles 655, etc. on the line 2h of the head 62 project droplets of ink at the times indicated in FIG. 15E.

[0057] Thus, when a line of printing is made with the recording head, the ink jet head 61 prints dots n1, n2, n3, n4, . . . as in FIG. 5 through the three-phase driving and the ink jet head 62 prints dots m1, m2, m3, m4, . . . through the three-phase driving, so that one line can be printed at dot pitch P in the main scanning direction. That is, the ink jet heads 61 and 62, while each having a dot pitch of 2P in the main scanning direction, can make printing at twice the resolution determined by that dot pitch.

[0058] If the spacing d between the lines 1d and 2d of the heads 61 and 62 is set such that $d = n \times 5D$ ($n \geq 1$), then a dot line printed by the head 61 can be superimposed upon a dot line by the head 62 because the timing of application of the drive voltage waveforms shown in FIGS. 15A to 15E are determined based on the pitch D in the sub-scanning direction. In this case, there is no problem. In practice, however, misalignment will occur between the dot lines printed by the heads 61 and 62 due to irregularities in the thickness of the substrate 63 and/or the adhesive layer.

[0059] When the amount of misalignment between the line of dots n1, n2, n3, . . . printed by the head 61 and the line of dots m1, m2, m3, . . . printed by the head 62 is in excess of one-half of the dot pitch in the sub-scanning direction, similar control to that in the above-described embodiments allows the amount of misalignment to be reduced below one-half of the dot pitch in the sub-scanning direction.

[0060] In this embodiment, since one dot pitch in the sub-scanning direction is further subdivided the accuracy of printing position can be increased in comparison with the above-described embodiments in which the ink nozzles are staggered for every three nozzles. However, in the five-phase driving for one line of printing, the printing speed becomes slower than in the three-phase driving.

[0061] Thus, the choice of the three-phase driving or the five-phase driving depends on tradeoff between the printing speed and the accuracy of printing position.

[0062] Next, a fourth embodiment of the present invention will be described with reference to FIGS. 17, 18 and 19.

[0063] In FIG. 17, 71, 72 and 73 denote ink jet heads for projecting cyan ink, magenta ink, and yellow ink, respectively. The cyan ink jet head 71 and the magenta ink jet head 72 are attached to both sides of a substrate 74 with adhesive, and the magenta ink jet head 72 and the yellow ink jet head 73 are attached to both sides of a substrate 75 with adhesive, thereby forming one color print head assembly.

[0064] As shown in FIG. 18, the ink jet heads 71, 72 and 73 are formed with ink nozzles 761 to 769, . . . , 771 to 779, . . . , and 781 to 789, . . . each of which is associated with a respective one of ink chambers. These ink nozzles are placed in a staggered arrangement for every three nozzles. That is, the ink nozzles 761 to 769, . . . of the ink jet head 71 are arranged at regular intervals of pitch P in the main scanning direction perpendicular to the direction of movement of the recording medium indicated by an arrow.

[0065] In the ink jet head 71, the ink chambers are divided into three sets each including every third head. That is, the ink nozzles 761, 764, 767, etc. form a first set. The nozzles 762, 765, 768, etc. form a second set, and the nozzles 763, 766, 769, etc. form a third set. The ink nozzles 761, 764, 767, etc. in the first set to which reference is made are arranged on a line ca. The ink nozzles 762, 765, 768, etc. in the second set are arranged on a line cb which is offset from the line ca by given pitch D in the sub-scanning direction. The ink nozzles 763, 766, 769, etc. in the third set are arranged on a line cc which is offset from the line cb by the pitch D in the sub-scanning direction.

[0066] In the ink jet head 72 as well, the ink chambers are divided into three sets each including every third head. That is, the ink nozzles 771, 774, 777, etc. form a first set. The nozzles 772, 775, 778, etc. form a second set, and the nozzles 773, 776, 779, etc. form a third set.

[0067] In the ink jet head 73, each of the nozzles 781 to 789, etc., which are arranged at regular intervals of pitch P in the main scanning direction, is aligned with a corresponding one of the nozzles 761 to 769, etc. in the head 71 in the sub-scanning direction. The ink nozzles 781, 784, 787, etc. in the first set are arranged on a line ya which is spaced apart from the reference line ca by distance d2 in the sub-scanning direction. The ink nozzles 782, 785, 788, etc. in the second set are arranged on a line yb offset from the line ya by given pitch D in the sub-scanning direction. The ink nozzles 783, 786, 789, etc. in the third set are arranged on a line yc offset from the line yb by the pitch D in the sub-scanning direction.

[0068] The ink jet heads 71, 72 and 73 are each arranged to provide drive voltage waveforms to their respective ink chambers at the times indicated in FIGS. 4A, 4B and 4C as in the first embodiment, thus performing three-phase driving. That is, the ink nozzles 761, 764, 767, etc. on the line ca of the head 71, the ink noz-

ink projection.

[0081] A seventh embodiment of the present invention will be described next with reference to FIG. 24.

[0082] As shown in FIG. 24, for example, four ink jet heads 911, 912, 913 and 914, each equipped with a large number of ink chambers, are arranged such that they are in parallel with each other in the direction indicated by an arrow in which a recording medium moves, i.e., in the sub-scanning direction and are spaced apart from each other by predetermined distance in the main scanning direction perpendicular to the direction in which the recording medium moves, thereby forming a serial print head assembly.

[0083] In each of the ink jet heads 911 to 914 of the serial print head assembly, the ink nozzles are staggered for every three nozzles and the ink chambers are divided into three sets each including every third chamber. When reference is made to a line 1i on which a first set of ink nozzles 92 in the leftmost head 911 are arranged, a line 2i on which a first set of ink nozzles 93 of the head 912 are arranged is spaced apart by distance d1 from the line 1i. A line 3i on which a first set of ink nozzles 94 of the head 913 are arranged is spaced apart by distance d2 from the line 1i. A line 4i on which a first set of ink nozzles 95 of the head 914 are arranged is offset by distance d3 from the line 1i.

[0084] This type of serial print head assembly is arranged to move in the main scanning direction with a recording medium stopped to thereby print multiple lines of dots at a time.

[0085] The print head assembly forms a color serial print head when the heads 911, 912, 913 and 914 are used as heads for cyan, magenta, yellow, and black, respectively.

[0086] When dots printed by the heads 911, 912 and 913 are out of register in the main scanning direction, the order in which the drive voltage waveforms shown in FIGS. 4A, 4B and 4C are selected can be changed as in the first embodiment, i.e., the timing of ink projection from the ink nozzles can be changed for each set of ink nozzles in the heads 911, 912 and 913 to correct the registration error of dots in the main scanning direction.

[0087] Next, detailed configurations of the ink jet heads in the embodiments thus far described will be described.

[0088] FIGS. 25A and 25B show an ink jet head of the type that heats ink in the ink chambers and then projects it. Grooves of U-shaped cross section are formed in one surface of a substrate 101 at predetermined pitch. The grooves are covered on top with a board 102 and covered in front with an orifice plate 104 formed with ink nozzles 103, thus forming a large number of ink chambers 105. Within each ink chamber are formed a heating element 106 and electrode patterns 107 and 108 for energizing the heating element, which, in turn, are covered with a protective coating 109.

[0089] In this type of ink jet head, application of a drive

pulse to the heating element 106 through the electrode patterns 107 and 108 rapidly heats ink within the ink chamber, so that it boils and forms a bubble of vapor, thus allowing a droplet of ink to be ejected from the ink nozzle.

[0090] Constructing a line print head from such ink jet heads would require a considerable amount of electric power when a large number of heating elements are driven at the same time, resulting in an increase in the size of a power supply used. The time-division driving of the ink chambers reduces the number of heating elements that are driven at the same time, allowing the supply amount of electric power to be reduced and hence the size of power supply to be reduced. If, when such time-division driving is performed, the ink jet heads are configured and controlled as in the previously described embodiments, the alignment error of dots can be corrected. This is the case with the time-division driving of a serial print head.

[0091] FIGS. 26A and 26B show an ink jet head of the type that ejects ink within ink chambers by mechanical vibrations of a piezoelectric material. Grooves of U-shaped cross section are formed in one surface of a substrate 111 made of a piezoelectric material, when an actuator that is polarized in the direction of an arrow is formed in the middle of each groove. Electrode patterns 113 and 114 are formed on the opposed surfaces of the actuator. The grooves are covered on top with a board 115 and covered in front with an orifice plate 117 formed with ink nozzles 116, thus forming a large number of ink chambers 118.

[0092] With this type of ink jet head, application of a drive pulse between the electrode patterns 113 and 114 causes mechanical deformation in the actuator 112, resulting in a change in the volume of the ink chamber. A change in the volume of the ink chamber involves a change in pressure in the ink chamber, allowing ink to be ejected from the nozzle.

[0093] Constructing a line print head or a serial print head from such ink jet heads and driving ink chambers on a time-division basis allow alignment error of dots to be corrected as in the previously described embodiments.

[0094] FIGS. 27A and 27B show an ink jet head of the type that ejects ink by mechanical vibrations of piezoelectric elements. Two polarized piezoelectric elements are glued together with their directions of polarization opposed to each other to form a substrate 121. U-shaped grooves are formed at predetermined pitch in one surface of the substrate across the two piezoelectric elements. An electrode pattern 122 is formed on the sidewalls and the bottom of each groove. The grooves are covered on top with a board 123 and covered in front with an orifice plate 125 formed with ink nozzles 124, thus forming a large number of ink chambers 126.

[0095] With this type of ink jet head, application of a drive pulse between the electrode pattern 122 of an ink chamber (center ink chamber) and the electrode pattern

ejected from ink nozzles of each set of ink chambers of the other heads than the reference head exceeds one-half of a dot pitch in the sub-scanning direction, changing the order in which the sets of ink chambers of the other heads are driven on a time division basis to reduce the amount of misalignment of dots below one-half of the dot pitch in the sub-scanning direction.

heads than the reference head exceeds one-half of a dot pitch in the main scanning direction, changing the order in which the sets of ink chambers in the other heads are driven on a time division basis to reduce the amount of misalignment of dots below one-half of the dot pitch in the main scanning direction.

7. A method of driving a recording head in which a plurality of ink jet heads (851, 852, . . . , 85n) each having a large number of ink chambers each provided with an ink nozzle are placed in a staggered arrangement on one side of a substrate (86) in a main scanning direction perpendicular to a direction in which a recording medium moves relative to the heads, characterized by comprising dividing the ink chambers of each of ink jet heads placed on the same side of the substrate into N (an integer of two or more) sets each including every N-th ink chamber, placing ink nozzles of N ink chambers each included in a respective one of the N sets in a staggered arrangement, driving the ink chambers on a time division basis for each set, and, when the amount of misalignment between dots recorded by droplets of ink ejected from ink nozzles of a set of ink chambers in a reference head of the heads placed on the same side and dots recorded by droplets of ink ejected from ink nozzles of each set of ink chambers of the other heads than the reference head exceeds one-half of a dot pitch in the sub-scanning direction, changing the order in which the sets of ink chambers of the other heads are driven on a time division basis to reduce the amount of misalignment of dots below one-half of the dot pitch in the sub-scanning direction.
8. A method of driving a recording head in which a plurality of ink jet heads (911, 912, . . . , 914) each having a large number of ink chambers each provided with an ink nozzle are arranged in parallel with each other in a sub-scanning direction in which a recording medium moves relative to the heads and are spaced apart from each other by a predetermined distance in a main scanning direction perpendicular to the sub-scanning direction, characterized by comprising dividing the ink chambers of each of the ink jet heads into N (an integer of two or more) sets each including every N-th ink chamber, placing ink nozzles of N ink chambers each included in a respective one of the N sets in a staggered arrangement, driving the ink chambers on a time division basis for each set, and, when the amount of misalignment between dots recorded by droplets of ink ejected from ink nozzles of a set of ink chambers in a reference head of the heads and dots recorded by droplets of ink ejected from ink nozzles of each set of ink chambers in the other

EUROPEAN SEARCH REPORT

Application Number
EP 99 10 3374

DOCUMENTS CONSIDERED TO BE RELEVANT			
Category	Citation of document with indication, where appropriate, of relevant passages	Relevant to claim	CLASSIFICATION OF THE APPLICATION (Int.Cl.6)
A	EP 0 425 285 A (SEIKO EPSON CORP) 2 May 1991 * the whole document *	1-8	B41J2/505
A	EP 0 005 844 A (IBM) 12 December 1979 * the whole document *	1-8	
A	PATENT ABSTRACTS OF JAPAN vol. 005, no. 166 (N-093), 23 October 1981 & JP 56 092076 A (NEC CORP), 25 July 1981 * abstract *	1-8	
A	EP 0 433 556 A (HEWLETT PACKARD CO) 26 June 1991 * abstract; figure 2 *	1-8	
A	US 5 644 344 A (HASELBY ROBERT D) 1 July 1997 * claim 3 *	1-8	
A	WO 96 32281 A (SILVERBROOK KIA ;EASTMAN KODAK CO (US)) 17 October 1996 * abstract; figure 7 *	1-8	TECHNICAL FIELDS SEARCHED (Int.Cl.6) B41J G06K
The present search report has been drawn up for all claims			
Place of search BERLIN		Date of completion of the search 18 May 1999	Examiner Nielsen, M
CATEGORY OF CITED DOCUMENTS X : particularly relevant if taken alone Y : particularly relevant if combined with another document of the same category A : technological background O : non-written disclosure P : intermediate document		T : theory or principle underlying the invention E : earlier patent document, but published on, or after the filing date D : document cited in the application L : document cited for other reasons a : member of the same patent family, corresponding document
